

Elastic Compute Service

Best Practices

Best Practices

Use OpenAPI to manage ECS

Use OpenAPI to Create Instance

In addition to the ECS Console or Buy Page, you can also use OpenAPI code to elastically create and manage ECS instances. This article describes how to create an ECS instance using Python.

When creating an ECS instance, pay attention to the following APIs:

- Create an ECS instance
- Query an instance list
- Start an ECS instance
- Allocate a public IP address

Create a Pay-As-You-Go ECS instance

Mandatory attributes:

- `SecurityGroupId`: Security group ID. A security group is used to implement the configurations of a group of instances based on firewall rules to protect the network access requests of the instances. It is recommended that only necessary access rules, rather than all access rules, be enabled when you configure security group access rules. You can create a security group on the ECS Console.
- `InstanceType`: Instance type. Refer to the ECS Buy Page. The option "one-core 2GB n1.small" indicates that the input parameter is "ecs.n1.small".
- `ImageId`: Image ID. Refer to the image list on the ECS console. You can filter public images or custom images.

For more parameter settings, refer to [Create an ECS instance](#).

Create an ECS instance

The following code shows creating an I/O optimized classic-network ECS instance with SSD as system

disk and "cloud_ssd" as disk parameter.

```
# create one after pay ecs instance.
def create_after_pay_instance(image_id, instance_type, security_group_id):
    request = CreateInstanceRequest()
    request.set_ImageId(image_id)
    request.set_SecurityGroupId(security_group_id)
    request.set_InstanceType(instance_type)
    request.set_IoOptimized('optimized')
    request.set_SystemDiskCategory('cloud_ssd')
    response = _send_request(request)
    instance_id = response.get('InstanceId')
    logging.info("instance %s created task submit successfully.", instance_id)
    return instance_id;
```

An instance ID is returned after the ECS instance is created successfully. If creation fails, an error code is returned. Since there are many parameters, you can make adjustments by visiting the [ECS Buy Page](#).

```
{"InstanceId":"i-****","RequestId":"006C1303-BAC5-48E5-BCDF-7FD5C2E6395D"}
```

ECS lifecycle

For details about the operations in different ECS status, refer to [ECS Instance Lifecycle](#).

Only when an instance is in the Stopped status, can the Start operation be performed, and only when it is in the Running status, can the Stop operation be performed. To query the ECS status, you can filter the instance list by inputting the parameter Instance ID. When you call `DescribeInstancesRequest`, input a JSON array of strings to query the resource status. When you query the status of a single instance, we suggest using `DescribeInstances` rather than `DescribeInstanceAttribute`, because the former API returns more attributes and content than the latter.

The following code is used to check the instance status. The system returns instance details only when the instance status conforms to the input parameters.

```
# output the instance owned in current region.
def get_instance_detail_by_id(instance_id, status='Stopped'):
    logging.info("Check instance %s status is %s", instance_id, status)
    request = DescribeInstancesRequest()
    request.set_InstanceIds(json.dumps([instance_id]))
    response = _send_request(request)
    instance_detail = None
    if response is not None:
        instance_list = response.get('Instances').get('Instance')
        for item in instance_list:
            if item.get('Status') == status:
                instance_detail = item
                break;
```

```
return instance_detail;
```

Start an ECS instance

After an ECS instance is created successfully, the default instance status is Stopped. To change to the Running status, send the Start command.

```
def start_instance(instance_id):  
    request = StartInstanceRequest()  
    request.set_InstanceId(instance_id)  
    _send_request(request)
```

Stop an ECS instance

To stop an ECS instance, just use the input instance ID.

```
def stop_instance(instance_id):  
    request = StopInstanceRequest()  
    request.set_InstanceId(instance_id)  
    _send_request(request)
```

Enable “ECS automatic startup” when creating an ECS instance

The ECS Start and Stop operations are asynchronous. You can perform the operation when the script is creating an ECS instance and detecting if it is in an appropriate status.

After you obtain the ID of a successfully created ECS instance, check whether the instance is in the Stopped status. If it is in the Stopped status, send the Start ECS command and wait until the ECS status changes to Running.

```
def check_instance_running(instance_id):  
    detail = get_instance_detail_by_id(instance_id=instance_id, status=INSTANCE_RUNNING)  
    index = 0  
    while detail is None and index < 60:  
        detail = get_instance_detail_by_id(instance_id=instance_id);  
        time.sleep(10)  
  
    if detail and detail.get('Status') == 'Stopped':  
        logging.info("instance %s is stopped now.")  
        start_instance(instance_id=instance_id)  
        logging.info("start instance %s job submit.")  
  
    detail = get_instance_detail_by_id(instance_id=instance_id, status=INSTANCE_RUNNING)  
    while detail is None and index < 60:  
        detail = get_instance_detail_by_id(instance_id=instance_id, status=INSTANCE_RUNNING);  
        time.sleep(10)  
  
    logging.info("instance %s is running now.", instance_id)
```

```
return instance_id;
```

Allocate a public IP address

If you specify the public network bandwidth when creating an ECS instance, you need to call an API to allocate a public IP address to the instance for public network access. For details, refer to [Allocate a public IP address](#).

Create an ECS instance in the Subscription mode

OpenAPI also supports creating ECS instances in the Subscription mode, in addition to Pay-As-You-Go ECS instances. The process for creating an ECS instance in the Subscription mode is different from that on Alibaba Cloud's website. Fees are automatically deducted for an ECS instance created in the Subscription mode. Before you create an ECS instance, ensure that you have sufficient account balance or credit amount, so that the fees can be deducted directly during creation.

When creating an ECS instance in Subscription mode, you only need to specify the payment option and duration. In the following code, the duration is set to one month.

```
request.set_Period(1) request.set_InstanceChargeType( 'PrePaid' )
```

The complete code for creating an ECS instance in the Subscription mode is as follows:

```
# create one prepay ecs instance.
def create_prepay_instance(image_id, instance_type, security_group_id):
    request = CreateInstanceRequest();
    request.set_ImageId(image_id)
    request.set_SecurityGroupId(security_group_id)
    request.set_InstanceType(instance_type)
    request.set_IoOptimized('optimized')
    request.set_SystemDiskCategory('cloud_ssd')
    request.set_Period(1)
    request.set_InstanceChargeType('PrePaid')
    response = _send_request(request)
    instance_id = response.get('InstanceId')
    logging.info("instance %s created task submit successfully.", instance_id)
    return instance_id;
```

Complete code

See the complete code as follows. You can use your resource parameters for configuration.

```
# coding=utf-8
# if the python sdk is not install using 'sudo pip install aliyun-python-sdk-ecs'
# if the python sdk is install using 'sudo pip install --upgrade aliyun-python-sdk-ecs'
# make sure the sdk version is 2.1.2, you can use command 'pip show aliyun-python-sdk-ecs' to check
```

```

    try:
        response_str = clt.do_action(request)
        logging.info(response_str)
        response_detail = json.loads(response_str)
        return response_detail
    except Exception as e:
        logging.error(e)

```

```
if __name__ == '__main__':  
    logging.info("Create ECS by OpenApi!")  
    create_instance_action()  
    # create_prepay_instance_action()
```

Manage instances

In addition to using Alibaba Cloud's ECS Console for resource creation and daily management, you can also use **OpenAPI** to manage and customize resources. OpenAPI allows you to manage and configure ECS instances with greater flexibility.

Alibaba Cloud encapsulates OpenAPI in an SDK to integrate ECS instance management into existing systems. This article describes how to manage ECS instances through OpenAPI based on Python development. You can develop ECS instances easily even if you do not have Python development experience.

Install the ECS Python SDK

Ensure that the Python runtime environment has been installed. This article uses Python 2.7+.

```
pip install aliyun-python-SDK-ecs
```

If you do not have the permission, switch to `sudo` to continue.

```
sudo pip install aliyun-python-SDK-ecs
```

The SDK version is **2.1.2**.

Hello Alibaba Cloud

Create the file **hello_ecs_api.py**. To use the SDK, first input your Alibaba Cloud access key ID and access key secret to instantiate an `AcsClient` object. You can obtain your access key at <https://ak-console.aliyun.com/>.

The access key ID and access key secret allow you to access Alibaba Cloud APIs and give you full access to this account. Ensure that you keep them safe.

```
from aliyunSDKcore import client  
from aliyunSDKecs.request.v20140526.DescribeInstancesRequest import DescribeInstancesRequest  
from aliyunSDKecs.request.v20140526.DescribeRegionsRequest import DescribeRegionsRequest  
clt = client.AcsClient('Your Access Key Id', 'Your Access Key Secret', 'cn-beijing')
```

You can develop your first application after the AcsClient object is instantiated. Query the list of regions that your account supports. For details, refer to [Query the list of available regions](#).

```
def hello_aliyun_regions():
    request = DescribeRegionsRequest()
    response = _send_request(request)
    region_list = response.get('Regions').get('Region')
    assert response is not None
    assert region_list is not None
    result = map(_print_region_id, region_list)
    logging.info("region list: %s", result)

def _print_region_id(item):
    region_id = item.get("RegionId")
    return region_id

def _send_request(request):
    request.set_accept_format('json')
    try:
        response_str = clt.do_action(request)
        logging.info(response_str)
        response_detail = json.loads(response_str)
        return response_detail
    except Exception as e:
        logging.error(e)

hello_aliyun_regions()
```

In the command line, run `python hello_ecs_api.py` to obtain a list of supported regions. The output is similar to the following:

```
[u'cn-shenzhen', u'ap-southeast-1', u'cn-qingdao', u'cn-beijing', u'cn-shanghai', u'us-east-1', u'cn-hongkong', u'me-east-1', u'ap-southeast-2', u'cn-hangzhou', u'eu-central-1', u'ap-northeast-1', u'us-west-1']
```

Query the list of ECS instances in the current region

The process for querying the instance list is similar to the region list. You only need to replace the input parameter `DescribeRegionsRequest` with `DescribeInstancesRequest`. For a full list of query parameters, refer to [Query an instance list](#).

```
def list_instances():
    request = DescribeInstancesRequest()
    response = _send_request(request)
    if response is not None:
        instance_list = response.get('Instances').get('Instance')
        result = map(_print_instance_id, instance_list)
        logging.info("current region include instance %s", result)

def _print_instance_id(item):
```

```
instance_id = item.get('InstanceId');
return instance_id
```

The output is as follows:

```
current region include instance [u' i- ', u' i- " ]
```

For a full list of APIs, refer to [ECS API overview](#). To query a list of disks, replace `DescribeInstancesRequest` with `DescribeDisksRequest`.

After the preceding task is completed, proceed to the next step for a new task. We will keep you updated on the topics below:

- Create API resources
- Manage resources based on TAG groups
- Renew APIs and set automatic renewal
- Release APIs and set the automatic release time

Complete code

```
# coding=utf-8
# if the python SDK is not install using 'sudo pip install aliyun-python-SDK-ecs'
# if the python SDK is install using 'sudo pip install --upgrade aliyun-python-SDK-ecs'
# make sure the SDK version is 2.1.2, you can use command 'pip show aliyun-python-SDK-ecs' to check

    hello_aliyun_regions()
    list_instances()
```

If you want to learn other API operations in ECS, refer to [ECS API operation](#).

Use OpenAPI to Release Instance

One important feature of ECS is on-demand resource creation. You can create custom resources elastically on demand during peak service hours, and then release those resources after service computing is completed. This article offers you several tips about how to easily release ECS instances and achieve elasticity.

This article involves the following important functions and related APIs:

- Release Pay-As-You-Go ECS instances
- Set the automatic release time for Pay-As-You-Go ECS instances
- Stop an ECS instance
- Instance list query API

After an ECS instance is released, the physical resources used by the instance are recycled, including disks and snapshots. The related data is completely lost and can never be recovered. If you want to retain the data, you are advised to create snapshots of disk data before releasing the ECS instance. The snapshots can be directly used to create a new ECS instance.

Release an ECS instance

Before you release an ECS instance, it is required that it is in the Stopped status. If any application is affected after the ECS instance is stopped, restart the instance.

Stop an ECS instance

The command used to stop an ECS instance in Pay-As-You-Go mode and subscription mode is simple and same. The stop command contains the parameter ForceStop. If it is set to "True" , the ECS instance is stopped directly but data is not necessarily written to a disk, similar to power failure. You can set this parameter to "True" if you only want to release the ECS instance.

```
def stop_instance(instance_id, force_stop=False):
    """
    stop one ecs instance.
    :param instance_id: instance id of the ecs instance, like 'i-***'.
    :param force_stop: if force stop is true, it will force stop the server and not ensure the data
    write to disk correctly.
    :return:
    """
    request = StopInstanceRequest()
    request.set_InstanceId(instance_id)
    request.set_ForceStop(force_stop)
    logging.info("Stop %s command submit successfully.", instance_id)
    _send_request(request)
```

Release an ECS instance

If you try to release an ECS instance without stopping it, the following error may be returned:

```
{"RequestId":"3C6DEAB4-7207-411F-9A31-6ADE54C268BE","HostId":"ecs-cn-
hangzhou.aliyuncs.com","Code":"IncorrectInstanceStatus","Message":"The current status of the resource does not
support this operation."}
```

When the ECS instance is in the Stopped status, you can release it. The release process is simple and involves the following parameters:

- InstanceId: Instance ID
- force: If this parameter is set to "True" , the ECS instance is released forcibly even when it is not in the Stopped state. Use caution when setting this parameter. Release by mistake may

impact your services.

```
python def release_instance(instance_id, force=False): ''' delete instance according instance id, only
support after pay instance. :param instance_id: instance id of the ecs instance, like 'i-***'. :param force:
if force is false, you need to make the ecs instance stopped, you can execute the delete action. If
force is true, you can delete the instance even the instance is running. :return: ''' request =
DeleteInstanceRequest(); request.set_InstanceId(instance_id) request.set_Force(force)
_send_request(request)
```

The following response is returned when an ECS instance is released successfully:

```
{ "RequestId" : " 689E5813-D150-4664-AF6F-2A27BB4986A3" }
```

Set the automatic release time for ECS instances

You can set the automatic release time for ECS instances to simplify instance management. When the set time is reached, Alibaba Cloud will release your ECS instance automatically.

Note:The automatic release time follows the ISO8601 standard in UTC time. The format is yyyy-MM-ddTHH:mm:ssZ. If the seconds place is not 00, it is automatically set to start from the current minute. Time range: 30 minutes to three years from the current time.

```
def set_instance_auto_release_time(instance_id, time_to_release = None):
'''
setting instance auto delete time
:param instance_id: instance id of the ecs instance, like 'i-***'.
:param time_to_release: if the property is setting, such as '2017-01-30T00:00:00Z'
it means setting the instance to be release at that time.
if the property is None, it means cancel the auto delete time.
:return:
'''
request = ModifyInstanceAutoReleaseTimeRequest()
request.set_InstanceId(instance_id)
if time_to_release is not None:
request.set_AutoReleaseTime(time_to_release)
_send_request(request)
```

Execute `set_instance_auto_release_time( 'i-1111' , '2017-01-30T00:00:00Z' )` to complete the time setting.

When the setting is successful, you can use `DescribeInstances` to query the automatic release time.

```
def describe_instance_detail(instance_id):
'''
describe instance detail
:param instance_id: instance id of the ecs instance, like 'i-***'.
:return:
'''
request = DescribeInstancesRequest()
```

```

request.set_InstanceIds(json.dumps([instance_id]))
response = _send_request(request)
if response is not None:
    instance_list = response.get('Instances').get('Instance')
    if len(instance_list) > 0:
        return instance_list[0]

def check_auto_release_time_ready(instance_id):
    detail = describe_instance_detail(instance_id=instance_id)
    if detail is not None:
        release_time = detail.get('AutoReleaseTime')
        return release_time

```

Cancel the automatic release

If you need to cancel the automatic release due to service changes, run the following command to set the automatic release time to null:

```
set_instance_auto_release_time('i-1111')
```

Complete code

Note: Use caution when releasing ECS instances.

```

# coding=utf-8

If you want to learn other API operations in ECS, refer to [ECS API operation](#).

Use OpenAPI to renew instances

In addition to the ECS Console or sales page, Alibaba Cloud provides APIs to renew instances and query and manage renewals.

This article involves the following important functions:

- Query ECS instances by expiration time
- Renew instances
- Query the automatic renewal time of an ECS instance
- Set the automatic renewal time of an ECS instance

Lifecycle is important to ECS instances in the Subscription mode. If you fail to renew your ECS instance on time, the instance may be locked or even released, thus affecting your service continuity. You can use APIs to view the resource expiration time and renew your instance or recharge your

account.

This article involves the following APIs:

- Instance list query API
- Instance renewal API

Query ECS instances that will expire within the specified time range

The instance list query API can be used to query the instances that will expire within the specified time range by setting the filter parameters `ExpiredStartTime` and `ExpiredEndTime`. The time parameters follow the ISO8601 standard in UTC time, using the format `yyyy-MM-ddTHH:mmZ`. The system returns the list of instances that will expire within the specified time range. If you need to filter by security group, just add the security group ID.

```
INSTANCE_EXPIRED_START_TIME_IN_UTC_STRING = '2017-01-22T00:00Z'
INSTANCE_EXPIRE_END_TIME_IN_UTC_STRING = '2017-01-28T00:00Z'

def describe_need_renew_instance(page_size=100, page_number=1, instance_id=None,
check_need_renew=True, security_group_id=None):
    request = DescribeInstancesRequest()
    if check_need_renew is True:
        request.set_Filter3Key("ExpiredStartTime")
        request.set_Filter3Value(INSTANCE_EXPIRED_START_TIME_IN_UTC_STRING)
        request.set_Filter4Key("ExpiredEndTime")
        request.set_Filter4Value(INSTANCE_EXPIRE_END_TIME_IN_UTC_STRING)
    if instance_id is not None:
        request.set_InstanceIds(json.dumps([instance_id]))
    if security_group_id:
        request.set_SecurityGroupId(security_group_id)
    request.set_PageNumber(page_number)
    request.set_PageSize(page_size)
    return _send_request(request)
```

Renew ECS instances

Only ECS instances in the Subscription mode can be renewed. Pay-As-You-Go instances cannot be renewed. Renewals must be paid by account balance or credit. Fee deduction and order creation are in sync with API execution. Ensure that there is sufficient balance in your account.

```
python def _renew_instance_action(instance_id, period='1'): request = RenewInstanceRequest()
request.set_Period(period) request.set_InstanceId(instance_id) response = _send_request(request)
logging.info('renew %s ready, output is %s ', instance_id, response)
```

Fees are automatically deducted when the instance is renewed. After the renewal is completed, you can use `InstanceId` to query the latest resource expiration time of the instance. Because the API is executed asynchronously, the expiration time is updated in 10 seconds.

Enable automatic ECS instance renewal

Alibaba Cloud introduces the automatic renewal function for ECS instances in the Subscription mode to help you reduce the cost of expired resource maintenance. Fee deduction for automatic renewal starts at 08:00:00 seven days before the expiration date. If fee deduction fails on the first day, the deduction process repeats on the following days in sequence until fees are deducted successfully or resources are locked after the seven-day period. Ensure that you have sufficient balance or credit amount in your account.

Query the automatic renewal setting

You can use OpenAPI to query and set automatic renewal. The API supports only ECS instances in the Subscription mode. If you use the API on a Pay-As-You-Go instance, an error will be returned. You can query the automatic renewal status of up to 100 ECS instances in the Subscription mode at a time. Use commas to separate multiple instance IDs.

The input parameter of DescribeInstanceAutoRenewAttribut is the instance ID.

- InstanceId: You can query up to 100 ECS instances in the Subscription mode at a time. Use commas to separate multiple instance IDs.

```
python # check the instances is renew or not
def describe_auto_renew(instance_ids, expected_auto_renew=True):
    describe_request = DescribeInstanceAutoRenewAttributeRequest()
    describe_request.set_InstanceId(instance_ids)
    response_detail = _send_request(request=describe_request)
    failed_instance_ids = ""
    if response_detail is not None:
        attributes = response_detail.get('InstanceRenewAttributes').get('InstanceRenewAttribute')
        if attributes:
            for item in attributes:
                auto_renew_status = item.get('AutoRenewEnabled')
                if auto_renew_status != expected_auto_renew:
                    failed_instance_ids += item.get('InstanceId') + ','
    describe_auto_renew('i-1111,i-2222')
```

The following content is returned:

```
python {"InstanceRenewAttributes":{"InstanceRenewAttribute":[{"Duration":0,"InstanceId":"i-1111","AutoRenewEnabled":false}, {"Duration":0,"InstanceId":"i-2222","AutoRenewEnabled":false}], "RequestId":"71FBB7A5-C793-4A0D-B17E-D6B426EA746A"}
```

If automatic renewal is set, the returned attribute AutoRenewEnabled is "True" . If automatic renewal is not set, the attribute is "False" .

Set/Cancel automatic renewal for ECS instances

Automatic renewal setting requires three input parameters:

- InstanceId: You can set automatic renewal for up to 100 ECS instances in the Subscription mode at a time. Use commas to separate multiple instance IDs.
- Duration (month): 1, 2, 3, 6, or 12.
- AutoRenew: "True" or "False" ("True" is enabling automatic renewal, and "False" is cancelling automatic renewal.

```
python def setting_instance_auto_renew(instance_ids, auto_renew = True): logging.info('execute
enable auto renew ' + instance_ids) request = ModifyInstanceAutoRenewAttributeRequest();
request.set_Duration(1); request.set_AutoRenew(auto_renew); request.set_InstanceId(instance_ids)
_send_request(request)
```

When the operation is successful, the following response is returned:

```
python {"RequestId":"7DAC9984-AAB4-43EF-8FC7-7D74C57BE46D"}
```

You can perform a query after successful renewal. The system will return the renewal duration and the status of automatic renewal (enabled/disabled).

```
python {"InstanceRenewAttributes":{"InstanceRenewAttribute":{"Duration":1,"InstanceId":"i-
1111","AutoRenewEnabled":true},{"Duration":1,"InstanceId":"i-
2222","AutoRenewEnabled":true}}, "RequestId":"7F4D14B0-D0D2-48C7-B310-B1DF713D4331"}
```

Complete code

```
# coding=utf-8

# if the python sdk is not install using 'sudo pip install aliyun-python-sdk-ecs'
# if the python sdk is install using 'sudo pip install --upgrade aliyun-python-sdk-ecs'
# make sure the sdk version is 2.1.2, you can use command 'pip show aliyun-python-sdk-ecs' to check

If you want to learn other API operations in ECS, refer to [ECS API operation](#).

User data

Customize yum repository, NTP service, and DNS service

User data is a type of script provided by Alibaba Cloud for users to customize the startup behaviors of ECS instances. For details, refer to [User data](#).

This document takes a Linux instance for example to introduce how to use user data to configure

your own yum repository, NTP service, and DNS service when creating a Linux instance. User data also enables you to configure NTP service and DNS service for a Windows instance.

Scenario

Currently, when a Linux instance is started, Alibaba Cloud automatically configures pre-defined yum repository, NTP service, and DNS service for the instance. However, if you want to have your own yum repository, NTP service, and DNS service, use user data to implement this requirement.

Note:

- If you are using a custom yum repository, Alibaba Cloud does not provide support for it.
- If you are using a custom NTP service, Alibaba Cloud does not provide time service.

Customize yum repository, NTP service, and DNS service

Follow the steps below to customize yum repository, NTP service, and DNS service for a Linux instance when creating it.

Log on to ECS Management Console and create an instance. Configure the instance as follows:

- **Network Type:** Select VPC.
- **Instance Type:** Select an I/O-optimized instance.
- **Operating System:** Select CentOS 7.2 in **Public Image** tab.
- **Security Setup:** Select one to meet your requirement.

Enter the following script in the **User Data** box on the instance creation page.

```
#!/bin/sh
# Modify DNS
echo "nameserver 8.8.8.8" | tee /etc/resolv.conf
# Modify yum repo and update
rm -rf /etc/yum.repos.d/*
touch myrepo.repo
echo "[base]" | tee /etc/yum.repos.d/myrepo.repo
echo "name=myrepo" | tee -a /etc/yum.repos.d/myrepo.repo
echo "baseurl=http://mirror.centos.org/centos" | tee -a /etc/yum.repos.d/myrepo.repo
echo "gpgcheck=0" | tee -a /etc/yum.repos.d/myrepo.repo
echo "enabled=1" | tee -a /etc/yum.repos.d/myrepo.repo
yum update -y
# Modify NTP Server
echo "server ntp1.aliyun.com" | tee /etc/ntp.conf
systemctl restart ntpd.service
```

Note:

- The first line must be `#!/bin/sh`, with no leading space.
- Do not add unnecessary spaces or carriage return characters in the full text.
- You can customize URLs of your own DNS server, NTP Server, and yum repository based on the instance situations.
- The preceding content applies to CentOS 7.2 images. If you are using other images, modify the user data, as needed.
- You also can define the yum repository in user data of the Cloud Config type, but it is not recommended because it is not flexible enough to get adapted to Alibaba Cloud that may pre-configure some yum repository. User data of script type is recommended for changing the yum repository.

User Data

Set User Data

Later Now ?

☐ The input has been base64 encoded

```
#!/bin/sh
# Modify DNS
echo "nameserver 8.8.8.8" | tee /etc/resolv.conf
# Modify yum repo and update
rm -rf /etc/yum.repos.d/*
touch myrepo.repo
echo "[base] | tee /etc/yum.repos.d/myrepo.repo"
```

Windows support bat and powershell formats, with base-64 encoding, the script starts with [bat] or [powershell]. Linux supporters shell script, for more format reference please see [cloudinit>>](#)

After the configuration is completed, click **Buy Now** and activate the instance following instructions on the page.

After the instance is created, you can log on to the instance to view the implementation details, as shown in the figure below.

```

```

The preceding figure shows that you have successfully customized the DNS service, the NTP service,

and the yum repository.

Create a new account with the root user privilege

User data is a type of script provided by Alibaba Cloud for users to customize the startup behaviors of ECS instances. For details, refer to [User data](#).

This document takes a Linux instance as an example to introduce how to use user data to create a new account with the root user privilege for a Linux instance when creating the instance. User data also enables you to create a new account with the administrator privilege for a Windows instance.

Scenario

Use user data of instances if you want to achieve the following results when creating a Linux ECS instance:

- Disable the default **root** account that comes with a Linux ECS instance. You can use the user data script to customize how to disable the root user and how many privileges of the root user to be disabled.
- Create a new account with the root user privilege and customize the account name.
- Use only SSH key pairs, but not user password, for remote logon to manage the instance using the newly-created account with the root user privilege.
- If this newly-created account requires performing some operations that only can be done by a user with root user privilege, the sudo command can be used without a password for privilege escalation.

Create a new account with the root user privilege

Follow the steps below to create a new account with the root user privilege.

Log on to ECS Management Console and create a Linux instance. Configure the instance as follows:

- **Network Type**: Select **VPC**.
- **Instance Type**: Select an I/O-optimized instance.
- **Operating System**: Select CentOS 7.2 in **Public Image** tab.
- **Security Setup**: select **Later**.

Enter the following script in the **User Data** box on the instance creation page:

```
#!/bin/sh
useradd test
echo "test ALL=(ALL) NOPASSWD:ALL" | tee -a /etc/sudoers
mkdir /home/test/.ssh
touch /home/test/.ssh/authorized_keys
echo "ssh-rsa
AAAAB3NzaC1yc2EAAAABJQAAAQEAhGqhEh/rGbIMCGItFVtYpsXPQrCaunGJKZVIWtINrGZwusLc290qDZ

TTSyJtCYUnEKxvcK+d1ZwxbNuk2QZ0ryHESDbSacZlNFgFQEDxhCrvko+zWLjTVnomVUDhdMP2g6fZ0tgF
VwkJFV0bE7oob3NOVcrx2TyhfcAjA4M2/Ry7U2MFADDC+EVkpoVDm0SOT/hYJgaVM1xMDISeE7kzX7yZ
bJLR1XAWV1xzZkNclY5w1kPnW8qMYuSwhpXzt4gsF0w== rsa-key-20170217" | tee -a
/home/test/.ssh/authorized_keys
```

Note:

- The first line must be `#!/bin/sh` with no leading space.
- Do not enter unnecessary spaces or carriage return characters in the text.
- The last line is your public key. You can define it.
- You can add other configuration in the script, as you need.
- The example script only applies to CentOS 7.2. If you are using other images, customize the script according to the operating system types.

User Data

Set User Data

☐ The input has been base64 encoded

```
#!/bin/sh
useradd test
echo "test ALL=(ALL) NOPASSWD:ALL" | tee -a
/etc/sudoers
mkdir /home/test/.ssh
touch /home/test/.ssh/authorized_keys
echo "ssh-rsa
AAAAB3NzaC1yc2EAAAABJQAAAQEAhGqhEh/rGbIMCGItFVtYpsXPQrCaunGJKZVIWtINrGZwusLc290qDZ

bJLR1XAWV1xzZkNclY5w1kPnW8qMYuSwhpXzt4gsF0w== rsa-key-20170217" | tee -a
/home/test/.ssh/authorized_keys
```

Windows support bat and powershell formats, with base-64 encoding, the script starts with [bat] or [powershell].
Linux supporters shell script, for more format reference please see [cloudinit](#)>>

After the preceding configuration is completed, click **Buy Now** and activate the instance following instructions on the page.

After the instance is created, you can use the newly-created **test** user to log on to the instance using an SSH private key. You can also escalate the permission using the `sudo` command and execute various operations that require the root user privilege, as shown in the figure.

```
test@iZwz9bm4vhpg7275w13w7eZ:/
Using username "test".
Authenticating with public key "rsa-key-20170217"

Welcome to Alibaba Cloud Elastic Compute Service !

```

Overview

Previously, applications deployed on an ECS Instance usually needed to use Access Key ID and Access Key Secret (AK) to access APIs of other Alibaba Cloud products. AK is the key to accessing Alibaba Cloud APIs and has all of the permissions of the corresponding accounts. In order to help applications manage the AK, you have to save AK in the configuration files of the application or save it in an ECS instance by using other methods, which makes it more complicated to manage the AK and reduces its confidentiality. What's more, if you need concurrent deployment across regions, the AK will be diffused along with the images or instances created by the image, which makes you have to update and re-deploy the instances and images one by one when changing the AK.

Now with the help of the instance RAM role, you can assign a RAM role to an ECS instance. The applications on the instance can then access APIs of other cloud products with the STS credential. The STS credential is automatically generated and updated by the system, and the applications can use the specified meta data URL to obtain the STS credential without special management. Meanwhile, you can modify the RAM role and the authorization policy to grant different or identical access permissions to an instance to different Alibaba Cloud products.

This article introduces how to create an ECS instance that plays a RAM role and how to enable the applications on the ECS instance to access other Alibaba Cloud products with the STS credential. In this article, the Python SDK on an ECS instance accessing an OSS bucket is used as the example. The detailed steps are as follows:

1. Create a RAM role and attach it to an authorization policy.
2. Create an ECS instance playing the RAM role to create.
3. Within the instance, access the metadata URL to obtain the STS credential.
4. Use the Python SDK to access OSS using the STS credential.

Operating procedure

1. Create a RAM role and attach it to an authorization policy

Use the `CreateRole` API to create a RAM role. The required request parameters are:

- **RoleName**: Specify a name for the role. *EcsRamRoleTest* is used in this example.
- **AssumeRolePolicyDocument**: Specify a policy as follows, which indicates that the role to be created is a service role and an Alibaba Cloud product (ECS in this example) is assigned to play this role.

```
{
  "Statement": [
    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "ecs.aliyuncs.com"
        ]
      }
    }
  ],
  "Version": "1"
}
```

Use the `CreatePolicy` API to create an authorization policy. The required request parameters are:

- **PolicyName**: Specify a name for the authorization policy. *EcsRamRolePolicyTest* is used in this example.
- **PolicyDocument**: Specify a policy as follows, which indicates that the role has OSS read-only permission.

```
{
  "Statement": [
    {
      "Action": [
        "oss:Get*",
        "oss:List*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ],
  "Version": "1"
}
```

Use the `AttachPolicyToRole` API to attach the authorization policy to the role. The required request parameters are:

- **PolicyType**: Set it to *Custom*.
- **PolicyName**: Use the policy name specified in step 2. Use *EcsRamRolePolicyTest* in this example.
- **RoleName**: Use the role name specified in step 1. Use *EcsRamRoleTest* in this example.

2. Create an ECS instance playing the RAM role

Prerequisites

A VPC network is available.

Operating procedure

Follow the steps to create an ECS instance playing the RAM role.

Use the `CreateInstance` API to create an ECS instance. The required request parameters are:

- **RegionId**: The region of the instance. In this example, *cn-hangzhou* is used.
- **ImageId**: The image of the instance. In this example, *centos_7_03_64_40G_alibase_20170503.vhd* is used.
- **InstanceType**: The type of the instance. In this example, *ecs.xn4.small* is used.
- **VSwitchId**: The virtual switch of the VPC network where the instance is located.

Because the instance RAM role only supports VPC network, `VSwitchId` is required.

- **RamRoleName**: The name of RAM Role. In this example, *EcsRamRoleTest* is used.

If you want to authorize a sub account to create an ECS instance playing the specified RAM role, besides the permission to create an ECS instance, the sub account must have the `PassRole` permission. Therefore, you must customize an authorization policy as follows and attach it to the sub account. If the action is creating an ECS instance only, set *[ECS RAM Action]* to `ecs:CreateInstance`. You can grant more permissions to meet your needs. For details, see [Actions in RAM that can be authorized to an ECS instance](#). If you want to grant all ECS action permissions to the sub account, set *[ECS RAM Action]* to `ecs:*`.

```
{
  "Statement": [
    {
      "Action": "[ECS RAM Action]",
```

```

"Resource": "*",
"Effect": "Allow"
},
{
  "Action": "ram:PassRole",
  "Resource": "*",
  "Effect": "Allow"
},
"Version": "1"
}

```

Set the password and start the instance.

Set the ECS instance to access the Internet by using API or on the ECS console.

To set an ECS instance in a VPC network to access the Internet on a console, see **Bind an Elastic IP address (EIP)** in the *Quick Start* of Virtual Private Cloud.

3. Access the metadata URL within the instance to obtain the STS credential

Follow the steps to obtain the STS credential of the instance.

Connect to the instance.

Access the following URL to obtain the STS credential.

<http://100.100.100.200/latest/meta-data/ram/security-credentials/EcsRamRoleTest>

The last part of the URL is the RAM role name, which must be replaced with the one you create.

In this example, we run the curl command to access the URL. If you are using a Windows ECS instance, see **Use metadata of an instance in ECS** in the *User Guide* to obtain the STS credential.

The return parameters are as follows.

```

[root@local ~]# curl http://100.100.100.200/latest/meta-data/ram/security-credentials/EcsRamRoleTest
{
  "AccessKeyId" : "STS.J8XXXXXXXXXX4",
  "AccessKeySecret" : "9PjfXXXXXXXXXBf2XAW",
  "Expiration" : "2017-06-09T09:17:19Z",
  "SecurityToken" : "CAIXXXXXXXXXXXwmBkleCTkyI+",
  "LastUpdated" : "2017-06-09T03:17:18Z",

```

```
"Code" : "Success"
}
```

4. Use the Python SDK to access OSS with the STS credential

In this example, with the STS credential, we use the Python SDK to list 10 files in an OSS bucket that is in the same region with the instance.

Prerequisites

- You have remotely connected to the ECS instance.
- Python has been installed on the ECS instance. If you are using a Linux ECS instance, pip must be installed.
- A bucket has been created in the region of the instance, and the bucket name and the Endpoint have been acquired. In this example, the bucket name is *ramroletest*, and the endpoint is *oss-cn-hangzhou.aliyuncs.com*.

Operating procedure

Follow the steps to use the Python SDK to access OSS.

Run the command `pip install oss2` to install OSS Python SDK.

If you are using a Windows ECS instance, see **Installation** in the *Python-SDK Reference of Object Storage Service*.

Run the following commands to test, of which:

- The three parameters in `oss2.StsAuth` must be set to the values of the return parameters: `AccessKeyId`, `AccessKeySecret`, and `SecurityToken`.
- The last two parameters in `oss2.Bucket` are the bucket name and the endpoint.

```
import oss2
from itertools import islice
auth = oss2.StsAuth(<AccessKeyId>, <AccessKeySecret>, <SecurityToken>)
bucket = oss2.Bucket(auth, <your Endpoint>, <your Bucket name>)
for b in islice(oss2.ObjectIterator(bucket), 10):
    print(b.key)
```

The output result is displayed as follows.

```
[root@local ~]# python
Python 2.7.5 (default, Nov 6 2016, 00:28:07)
```

```
[GCC 4.8.5 20150623 (Red Hat 4.8.5-11)] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import oss2
>>> from itertools import islice
>>> auth = oss2.StsAuth("STS.J8XXXXXXXXXX4", "9PjXXXXXXXXXBf2XAW",
"CAIXXXXXXXXXXwmBkleCTkyI+")
>>> bucket = oss2.Bucket(auth, "oss-cn-hangzhou.aliyuncs.com", "ramroletest")
>>> for b in islice(oss2.ObjectIterator(bucket), 10):
...     print(b.key)
...
ramroletest.txt
test.sh
```
